Context

- **Distinctive architectural design** Examples
  - **Aesthetic features** that provide utility beyond the mere use of the building
  - Similar to **consumption value of arts**
- **Internal value** to residents of a distinctive building
  - Reflected in rents to **owner of distinctive building**
- **External value** to neighbors (in addition to society as a whole)
  - Mostly reflected in rents to **owners of other buildings**
- **Coordination problem**
  - Private cost vs shared benefit incentivizes **freeriding**
- Scope for **welfare-improving planning policies**
  - Subsidies to owners implementing distinctive design
  - Zoning (distinctive districts, FAR incentives)

This paper

- **Develop a quantitative model** for the analysis of design policies
  - Downward-sloping demand for distinctive design meets increasing marginal cost
  - Design spillover shifts location-specific amenity
- **Review evidence** to guide quantification of the model
  - Internal design premium: 15%; External design premium: 9%
- **Survey** to understand design preferences
  - Buildings rated highly by Starchitect are valued higher by respondents
  - Dispersion of tastes for architecture similar to location preferences: $\epsilon = 4$
- **Simulate design policies** (within synthetic data)
  - Optimal Subsidy (10% of construction cost) improves welfare
  - Design districts can generate small improvements when they are small
  - FAR incentives require strong constraints that depreciate welfare
  - Super developers trade internalization of spillovers against monopoly rent

Related literature

- **Design premiums**
  - e.g. Hough and Kratz (1983); Vandell and Lane (1989); Ahlfeldt and Holman (2018); Been et al. (2016); Koster et al. (2016); Lindenthal and Johnson (2021); Füß et al. (2025), Herrera (2026)
    - Our quantitative survey covers 68 estimates of premiums from **41 studies**
    - Our quantitative survey covers 33 estimates of external premiums from **28 studies**
- **Quantitative urban models**
  - in tradition of Ahlfeldt et al. (2015); Redding (2025) for summary
    - We focus on choices among buildings of different design within a neighborhood
- **Welfare effects of planning**
  - e.g. Glaeser et al. (2005); Brueckner and Rossi-Hansberg (2010); Brueckner and Sridhar (2012); Turner et al. (2014); Cheshire and Dericks (2020); Ahlfeldt et al. (2026)
    - Design choice by the developer is endogenous in our model

Model

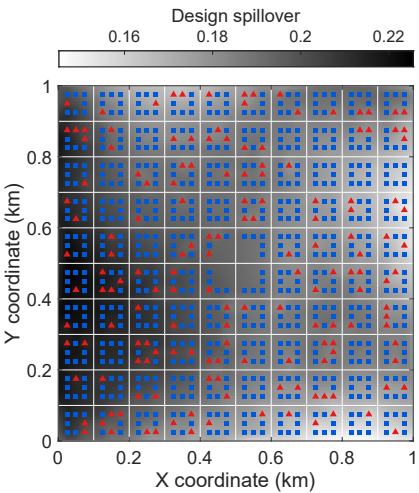
- **Geography:** Neighbourhood with J parcels and one developer per parcel
  - Each parcel has developable land $\bar{K}_i$, can be developed with one building
  - Inner ring to be developed, outer ring with fixed built fabric; embedded in wider city
- **Residents:** Choose **a building** (either distinctive or not) or the rest of the city
  - Standard Cobb-Douglas preferences for housing and floor space
  - Amenity B_i includes exogenous component and **design spillovers** D_i
    - Take the standard market potential form (normalized to range between 0 and 1)
  - Idiosyncratic preferences (Fréchet) for submarkets
    - **Downward-sloping demand** within submarkets: Distinctive, ordinary, rest of city
- **Developers:** Choose building height h_i and **design** d
  - Face design-specific construction cost and height elasticity of cost θ
    - Heterogeneity in design cost generates **upward-sloping aggregate supply**
  - May receive subsidy t_i^d and face design regulation G_i

Primitives and endogenous outcomes

- **Equilibrium:**
  - (Expected) Utility equalizes within neighbourhood
  - Developers choose profit-maximising height and design
  - Floor-space markets clear
- **Primitives:**
  - Calibrated/estimated parameters, neighbourhood wage, utility in rest of city
  - Parcel-specific fundamental amenity, design subsidy, height limit, design restriction
  - City population (by group in extension), parcel land
- **Endogenous outcomes:**
  - Submarket population (by group in extension), expected city utility, developer profits
  - Parcel rent, height, floor space consumption, distinctive design status & spillover
- **Mapping from primitives to endogenous outcomes**, solved numerically

Workers Developers Welfare Equilibrium

Intuition and quantification

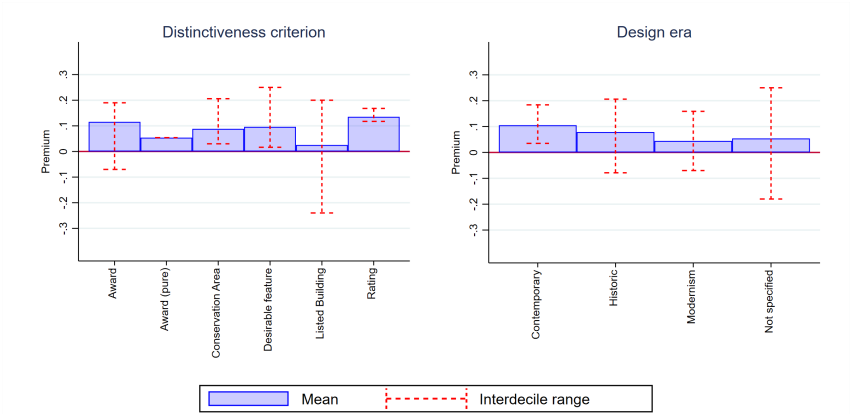


- Developers develop distinctive buildings **where it is profit-maximizing**
- **Marginal parcel** is where the return to distinctive design falls below the cost
- Exposure to distinctive design **spillover translates into higher prices**
- **Need moments to calibrate the model**
  - Internal design premium
  - External design premium
  - Taste dispersion

Neighbourhood and outer ring

Internal design premium

- Literature search reveals 68 estimates from 41 studies



Internal design premium

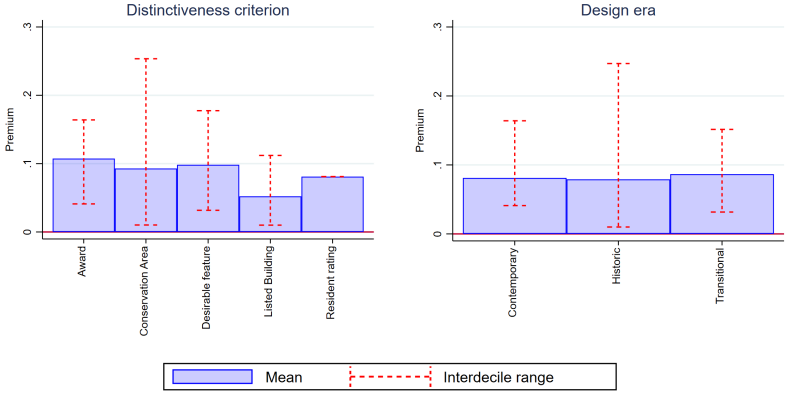
	(1) Premium		(2) Premium		(3) Premium	
Commercial	0.095***	(0.02)	0.101***	(0.02)	0.146***	(0.02)
Residential	0.077***	(0.02)	0.099**	(0.04)	0.164***	(0.04)
Conservation Area			-0.02	(0.03)		
Listed Building			-0.08*	(0.05)		
Award (pure)			-0.05	(0.04)		
Historic Style			0.010	(0.05)		
Weighted	No		No		Yes	
Sample	All		All		Cohort control	
r2	0.4		0.4		0.7	
N	68		68		17	

Notes: Standard errors in parentheses. Each observation is an estimate of the effect of distinctive design on property price or rent from the literature in log points. All explanatory variables are dummy variables. Baseline distinctiveness measure is listed building. Modern covers the style groups contemporary, modernism, and transitional from Figure 12 (right panel). Quality weights are proportionate to Google citation counts, regression adjusted for publication years. * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$

- Regression-based average
  - We weight observation by publication-year adjusted citation count
  - Most credible estimates are from studies that identify the distinctiveness effect within cohorts
  - **Internal design premium $\approx$ 15 %**

External design premium

- Literature search reveals 33 estimates from 28 studies: **Average** $\approx$ **9%**



Design preferences

- **Internet survey** asking respondents to rate 10 buildings on a 0-100 scale
  - Also obtained ratings by "Starchitect" Stefano Boeri (Bosco Verticale, Milan)
- Structural estimation of **Fréchet shift and share parameters** using GMM: $\epsilon = 4$
  - Buildings rated highly by Starchitect also appreciated by respondents ($\rho = 0.8$)

Group	Mean rating	Variance	Shift A_b	Shape ε
All respondents, all buildings	52.72	480.88	42.73	4.04
People similar to Starchitect	51.34	416.81	39.53	4.06
People different from Starchitect	52.99	586.57	42.16	3.79
Buildings ranked high by Starchitect	65.63	486.86	55.89	4.69
Buildings ranked low by Starchitect	39.80	474.90	32.39	3.40

Notes: This table reports GMM estimates based on matching the first and second moments of the building-level rating distributions to those implied by a Fréchet model. The shape parameter ε governs preference heterogeneity, while A_b reflects the building-specific location shift. Groups are defined based on respondent-level or Starchitect-level ranking similarity.

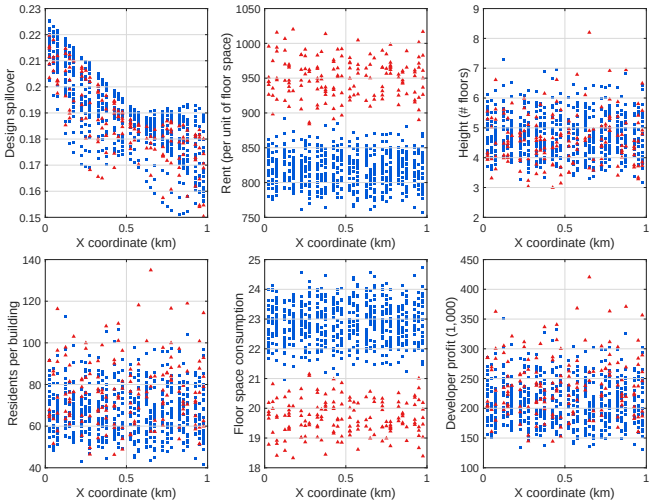
Examples GMM

Quantification

- **Borrow canonical parameters** from literature
  - Housing expenditure ($1 - \alpha = 0.33$), spillover decay ($\tau = 5$), height elasticity of construction cost ($\theta = 0.2$)
- **Estimate taste dispersion** using survey data
  - $\epsilon = 4$
- **Structural interpretation** of external design premium (for given $1 - \alpha$)
  - Normalize design spillover so that 1 reflects a fully distinctive neighbourhood
- Use **SMM** to estimate the average taste for and cost of distinctive design
  - The internal design premium via Frechet scale parameter
  - The average cost of distinctive design via target share of distinctive buildings (20%)
- This approach **works for real-world neighbourhoods**, too!

SMM

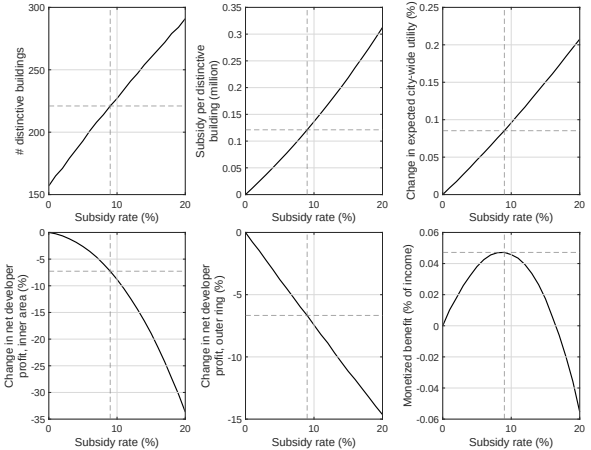
Neighbourhood structure



- Distinctive design premium
  - Matched to data
- Affects floorspace consumption
  - Higher price $\Rightarrow$ lower consumption
- Design spillover is greatest toward the border to the west area
  - Affects prices (effect barely visible)

Neighbourhood and ring

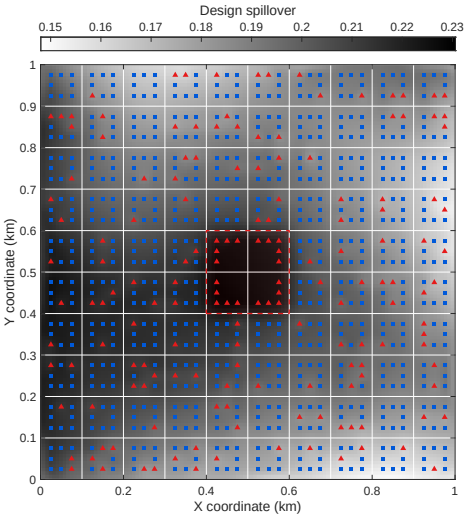
Pigovian subsidy



- Increases
  - # distinctive buildings
  - Expected utility
  - Developer gross profits
- Reduces net profits after taxes
  - Convex shape
- Hump-shaped welfare effect
  - Monetized utility effect, developer profits, and tax cost
  - Downward-sloping demand $\Rightarrow$ concavity
- **Optimal subsidy**:
  - 9% (6-12%) of construction cost
  - $\approx \frac{1}{3}$ of distinctive design cost

Subsidy gradients | Sensitivity

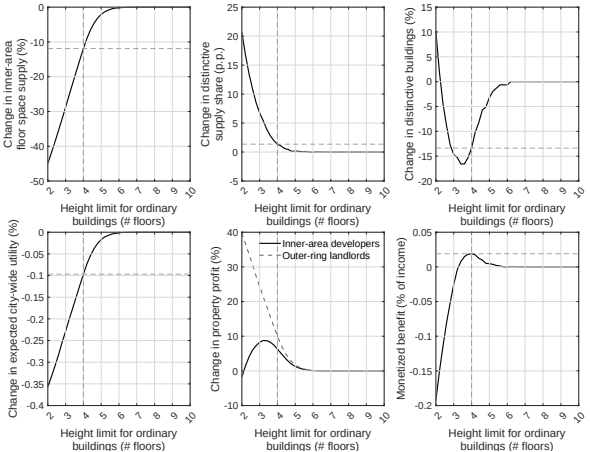
Mandatory distinctive design district



- Can **force developers** to solve the coordination problem
  - All buildings in a district must be distinctive
  - Related policy: Conservation areas
- **Wefare effects**
  - **Generally negative**: Cost of distinctive design dominates at the margin
  - **Positive at plaza** where externalities reach farther
    - If it is too large, the effect is negative due to diminishing returns

Map large district | Gradient | Gradient: Large district

FAR incentives



- **FAR incentives** only work under **constraints** for ordinary buildings
  - Introduce height limit for ordinary buildings
  - No limit for distinctive buildings
  - Policy only works if supply constraints are binding
- **Knife-edge welfare gain**
  - At 4-floor height limit
    - Driven by landlords, not workers!
  - Little effect ≥ 5
  - Tighter constraints (< 3) depreciate aggregate welfare (supply effect)

Gradients

Super developer

- **Coordination via super-developer:**
  - Have an incentive to internalize spillovers
  - Also have an incentive to maximize monopoly rent from scarce, distinctive design...
- **Positive effect on distinctive supply** compared to myopic developer, **but**:
  - Welfare effect lower and mostly appropriated by developers
  - Monopoly quantity setting partially offsets the incentive to internalize spillovers
  - **Policy can backfire** if the developer does not (fully) anticipate spillovers

Scenario comparison	Dist. supply	Supply	Rents	Expected utility	Pop	Profits	Net-benefit (% of inc.)
Myopic → Strategic	+18.43%	+0.04%	+0.04%	+0.01%	+0.16%	+0.94%	+0.04%
Strategic → w/o spillover	-21.67%	-0.19%	-0.04%	-0.02%	-0.24%	-1.37%	-0.06%

Notes: The table reports equilibrium outcomes under three super-developer scenarios using the greedy algorithm. Under the *fully-myopic* scenario the super developer makes sequential parcel choices based on fixed rents and historical spillover. The *fully-strategic* developer is a monopolist who anticipates current equilibrium spillovers. In the *strategic without spillover* scenario, the developer is a monopolist with given spillovers. Profits accrue to the inner-area super developer; fixed-ring landlords are excluded. Monetized net-benefit includes household gains and inner-area plus fixed-ring profit changes, as a percentage of starting-scenario income.

Heterogenous workers

- **Two worker groups** $k \in \{1, 2\}$
  - *Archiphiles* with $\frac{A^{D1}}{A^{O1}} > \frac{A^{D2}}{A^{O2}}$ and $\beta^1 > \beta^2$ vs. other workers
  - Ratios informed by respondents similar and different from *starchitect*
- Realistic (imperfect) sorting requires location **idiosyncratic preference shocks**
  - Nested **Fréchet** shocks distinguish substitution within (η) and across designs (ϵ)
  - Closed-form solutions for location choice probabilities (by group) as in QSM
  - $\eta = 100$ resembles bid-rent model: **high within-neighbourhood worker mobility**
  - $\eta = 8$, canonical in QUM: Affects **amenity value** and **developer** behaviors
- Nested numerical solution algorithm
  - Solve numerically for rent Q as a fixed point conditional on design allocation
  - Developer considers design switch based market-clearing alternative design rent

Preference shocks Location choice Survey evidence

Welfare effects by worker group

	$\eta = 100$		$\eta = 8$	
Neighbourhood sorting				
Archiphiles in distinctive buildings (%)	62.193		61.802	
Archiphiles in ordinary buildings (%)	7.835		8.963	
Archiphile spillover gradient	44.644		9.357	
Optimal subsidy (%)	10		21	
Optimal ordinary height cap (floors)	3.8		5.0	
Utility change (percent)	Archiphiles	Others	Archiphiles	Others
Subsidy 100 8	0.31526	0.03374	1.29659	-0.00578
FAR incentives 100 8	-0.05303	-0.09536	-0.00004	-0.00032
Distinctive district: full plaza	0.00970	-0.00273	0.02802	-0.00269
Fully strategic super developer	0.11031	-0.01338	0.65035	-0.08155

Archiphiles may benefit at the expense of others who value distinctive design less

Conclusion

- Distinctive architectural design generates substantial **positive externalities**
  - Market fails to deliver optimal design levels
- **Net social benefit** of additional distinctive design justifies **policy intervention**
  - **Most efficient:** Construction cost subsidy targeted at distinctive buildings
  - **Design standards** in moderate districts can leverage spillovers
  - **FAR bonuses** offer marginal gains and risk inefficiencies if miscalibrated
  - **Super developers** help IFF spillovers are correctly anticipated
- **Archiphiles may benefit at the expense** of others
  - Pigouvian subsidy most likely to benefit all worker groups
- Scope for future research
  - Interaction of distinctive design and urban context
  - Cost of distinctive design

Milan

Distinctive

Context

Workers: Preferences and indirect utility

- Workers choose among submarkets:
  - $\mathbf{C} = \{\text{distinctive}, \text{ordinary}, \text{outside}\}$
- Utility:
  - $U(v) = \tilde{U}^d a^d(v)$
  - $a^d(v)$ captures idiosyncratic taste for submarket d
- Within-neighbourhood utility:
  - $\tilde{U}^d = B_i \left(\frac{g}{\alpha}\right)^{\alpha} \left(\frac{f_i^d}{1-\alpha}\right)^{1-\alpha}$
- Housing demand:
  - $f_i^d = (1-\alpha)\frac{\bar{w}}{Q_i^d}$
- Indirect utility:
  - $\tilde{V}^d = A^d B_i^d \frac{\bar{w}}{(Q_i^d)^{1-\alpha}}$

Workers: Choice probabilities and outside option

- Idiosyncratic tastes:
  - $a^d(v) \sim$ Fréchet(A^d, ε)
  - Shape parameter ε governs taste dispersion
- Choice probabilities:
  - $\mu^d = \frac{(\tilde{V}^d)^\varepsilon}{\sum_{u \in \mathbf{C}} (\tilde{V}^u)^\varepsilon}$
- Outside option:
  - $\tilde{V}^{outside} = \bar{V}$
- Interpretation:
  - Higher amenity and lower rents increase market share
  - Larger ε implies more homogeneous preferences
- Key implication:
  - Generates downward-sloping demand for distinctive buildings

Workers: Design spillovers and local amenity

- Local amenity:
  - $B_i^d = b_i^d \cdot \exp[\beta D_i]$
- Design spillover:
  - $D_i = \frac{\sum_{z \neq i} \omega_{iz} \mathbf{1}(\tilde{d}_z = \text{distinctive})}{\max_i \left(\sum_{z \neq i} \omega_{iz} \right)}$
- Spatial weight:
  - $\omega_{iz} = (\bar{K}_z h_z) \exp(-\tau \mathcal{D}_{iz})$
- Interpretation:
  - Nearby distinctive buildings raise local amenities and rents
  - Larger nearby buildings generate stronger spillovers
  - Spillovers decay with distance
- Coordination problem:
  - Developers ignore benefits to neighbouring parcels

Back to Model

Developers: Technology and profits

- One developer per parcel i
  - Chooses building design $d \in \{\text{distinctive}, \text{ordinary}\}$
  - Chooses height h_i^d on parcel land $\bar{K}_i$
- Revenue:
  - $Q_i^d h_i^d \bar{K}_i$
  - Q_i^d is the unit price of floor space
- Construction cost:
  - $\bar{C}(h_i^d)^{1+\theta} \exp(\delta_i^d - t_i^d)\bar{K}_i$
  - θ governs how construction costs rise with height
  - δ_i^d is a design-specific cost shifter
  - t_i^d is a construction-cost subsidy
- Profit:
  - $\pi_i^d = \left[Q_i^d h_i^d - \bar{C}(h_i^d)^{1+\theta} e^{\delta_i^d - t_i^d} \right] \bar{K}_i$

Developers: Height and design choice

- Profit-maximising height:
  - $h_i^{d*} = \left(\frac{Q_i^d}{(1+\theta)\bar{C} e^{\delta_i^d - t_i^d}} \right)^{1/\theta}$
- Height regulation:
  - $\tilde{h}_i^d = \min(h_i^{d*}, \bar{h}_i^d)$
  - $\bar{h}_i^d$ is the design-specific height limit
- Design choice:
  - If $G_i =$ distinctive: planner requires distinctive design
  - Else: developer chooses
    - $\tilde{d}_i = \arg\max_{d \in \mathbf{D}} \pi_i^d$
- Floor-space supply:
  - $H_i^d = \tilde{h}_i^d \mathbf{1}(\tilde{d}_i = d) \bar{K}_i$
- Key mechanism:
  - Developers internalize own rents, but not spillovers on neighbouring parcels

Back to Model

Welfare

- Two welfare components:
  - Worker utility: $\mathbb{E}[U]\bar{N}$
  - Developer profits:
    - $\Pi = \sum_{i,d} \pi_i^d \mathbb{1}(\tilde{d}_i = d) + \bar{\pi}^{outside}$
- Expected utility:
  - $\mathbb{E}[U] = \Gamma\left(\frac{\varepsilon-1}{\varepsilon}\right)\left(\sum_{u\in\mathbf{c}}(\tilde{V}^u)^{\varepsilon}\right)^{1/\varepsilon}$
- Welfare metric:
  - Utility changes converted into income-equivalent units
  - Cobb-Douglas structure implies utility scales proportionally with income
- Policy evaluation:
  - $\Delta W = \frac{\mathbb{E}[U]^1 - \mathbb{E}[U]^0}{\mathbb{E}[U]^0}\bar{w}\bar{N} + \Delta\Pi$
- Subsidy cost:
  - $S = \sum_{i,d} \mathbf{1}(\tilde{d}_i = d)\bar{C}(h_i^d)^{1+\theta}\bar{K}_i\left[e^{\delta_i^d} - e^{\delta_i^d - t_i^d}\right]$

Back to Model

Equilibrium: Spatial equilibrium conditions

- Workers are mobile:
  - Across neighbourhoods via outside option (constant utility)
  - Across submarkets within neighbourhood (constant expected utility)
- Developers are competitive:
  - Take rents and spillovers as given
  - Choose profit-maximising design and height
- Floor-space markets clear at parcel level:
  - $f_i^d N_i^d = H_i^d$
- Submarket populations are consistent with discrete choice:
  - $\mu^d = \frac{1}{N} \sum_i N_i^d$
  - $\mu^d = \frac{(\tilde{V}^d)^\varepsilon}{\sum_{u \in \mathbf{C}} (\tilde{V}^u)^\varepsilon}$
- Spatial equilibrium:
  - Rents adjust such that demand equals supply across submarkets

Equilibrium: Recursive structure

- Conditional on:
  - $\{\tilde{d}_i, Q_i^d, \tilde{V}^{distinctive}, \tilde{V}^{ordinary}\}$
- Workers:
  - Housing demand: $f_i^d = (1-\alpha)\frac{\bar{w}}{Q_i^d}$
  - Choice probabilities: $\mu^d = \frac{(\tilde{V}^d)^\varepsilon}{\sum_{u \in \mathbf{C}} (\tilde{V}^u)^\varepsilon}$
- Developers:
  - Optimal height: $h_i^{d*} = \left(\frac{Q_i^d}{(1+\theta)\bar{C} e^{\delta_i^d - t_i^d}} \right)^{1/\theta}$
  - Feasible height: $\tilde{h}_i^d = \min(h_i^{d*}, \bar{h}_i^d)$
- Implied equilibrium objects:
  - Spillovers D_i, amenities B_i^d, supply H_i^d
  - Population N_i^d, utility $\mathbb{E}[U]$, profits Π

Equilibrium: Fixed-point problem

- Unknown equilibrium objects:
  - Design choices $\tilde{d}_i$
  - Rents Q_i^d
  - Submarket utilities $\{\tilde{V}^{distinctive}, \tilde{V}^{ordinary}\}$
- Submarket utilities pinned down by:
  - Population consistency: $\mu^d = \frac{1}{\bar{N}} \sum_i N_i^d = \frac{(\tilde{V}^d)^\varepsilon}{\sum_{u \in \mathbf{C}} (\tilde{V}^u)^\varepsilon}$
- Design choices pinned down by:
  - Profit maximisation: $\tilde{d}_i = \arg\max_{d \in \mathbf{D}} \pi_i^d$
- Rents pinned down by:
  - Parcel-level market clearing: $f_i^d N_i^d = H_i^d$
- Numerical solution:
  - Fixed point because spillovers affect both rents and design choices
  - Avoid multiplicity via convexification (heterogenous design cost)

Survey: Fréchet taste heterogeneity

- Survey data:
  - Respondents rate buildings on a 0–100 scale
  - Ratings interpreted as latent taste draws a_{ib}
- Structural assumption:
  - a_{ib} follows a Fréchet distribution
  - $F(a) = \exp\left(-(a/A_b)^{-\varepsilon}\right)$
- Parameters:
  - A_b: building-specific attractiveness
  - ε: taste heterogeneity across respondents
- Theoretical moments:
  - $\mathbb{E}[a_b] = A_b \Gamma\left(1 - \frac{1}{\varepsilon}\right)$
  - $\mathrm{Var}(a_b) = A_b^2 \left[\Gamma\left(1 - \frac{2}{\varepsilon}\right) - \Gamma\left(1 - \frac{1}{\varepsilon}\right)^2\right]$

GMM Estimation

- Empirical moments:
  - $\hat{\mu}_b = \frac{1}{n_b} \sum_{i=1}^{n_b} a_{ib}$
  - $\hat{\sigma}_b^2 = \frac{1}{n_b - 1} \sum_{i=1}^{n_b} (a_{ib} - \hat{\mu}_b)^2$
- Moment conditions:
  - $g_b^{\mu}(\theta) = \hat{\mu}_b - A_b \Gamma\left(1 - \frac{1}{\varepsilon}\right) = 0$
  - $g_b^{\sigma}(\theta) = \hat{\sigma}_b^2 - A_b^2 \left[\Gamma\left(1 - \frac{2}{\varepsilon}\right) - \Gamma\left(1 - \frac{1}{\varepsilon}\right)^2\right] = 0$
- Identification:
  - 20 buildings $\Rightarrow$ 40 empirical moments
    - Mean and variance for each building
  - 21 parameters (ε and 1 A_b per building) $\Rightarrow$ overidentified system
- Estimation method: One-step GMM with identity weighting matrix

Back to Preferences

SMM: Calibration targets

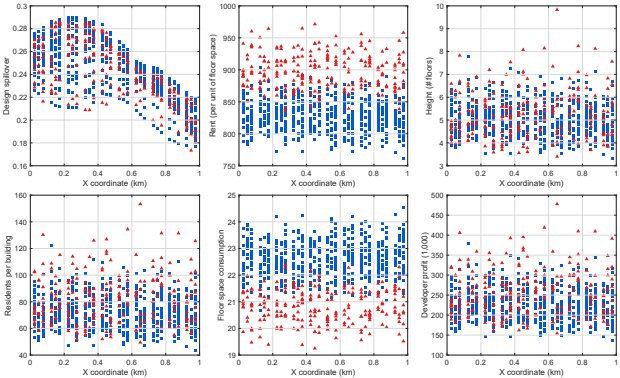
- Parameters to calibrate:
  - Preference for distinctive design: $A^{d=\text{distinctive}}$
  - Average distinctive design cost: $\bar{\delta}^{d=\text{distinctive}}$
- Distinctive design cost: Common component plus shock from normal distribution
  - $\delta_i^{d=\text{distinctive}} = \bar{\delta}^{d=\text{distinctive}} \left(1 + \sigma \frac{\tilde{\delta}_i}{\bar{\delta}^{d=\text{distinctive}}}\right)$
- Empirical target moments:
  - Internal design premium: $\hat{a} = 15\%$
  - Share of distinctive buildings: $\hat{s} = 20\%$
- SMM objective:
  - Match model-implied premium and distinctive share
  - Internal premium identifies preferences
  - Distinctive share identifies costs

SMM: Numerical procedure

- Inner loop:
  - Solve developer design choices and heights
  - Iterate until no parcel switches design
- Middle loop:
  - Update utilities and population shares
  - Clear housing markets across submarkets
- Outer loop:
  - Update structural parameters: $A^{d=\text{distinctive}}$,
    - $\bar{\delta}^{d=\text{distinctive}}$
- Numerical objective:
  - Minimize weighted distance between:
    - Simulated and empirical internal premium
    - Simulated and empirical distinctive share
- Main calibration:
  - $A^{d=\text{distinctive}} = 0.772$, $\bar{\delta}^{d=\text{distinctive}} = 0.219$

Back to Quantification

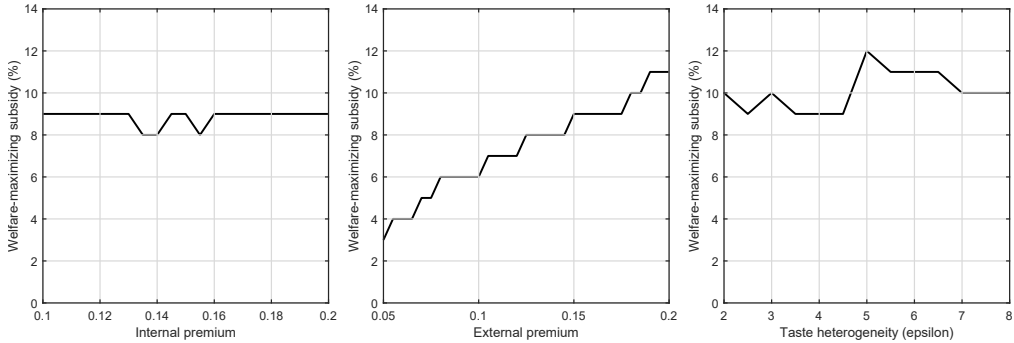
Subsidy Gradients



- Effects across subsidy levels:
  - Distinctive building share rises smoothly
  - Rents increase, but at diminishing rate
- Margins of adjustment:
  - Utility gain from spillovers
  - Developer profits vs. tax burden
- Welfare profile:
  - Concave, consistent with downward-sloping demand
  - Peak defines Pigovian optimum

Back to Pigovian subsidy

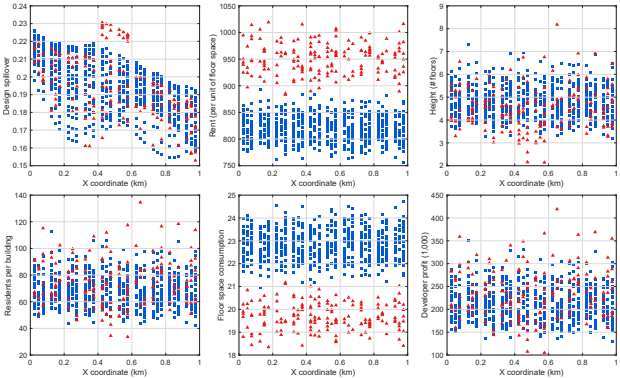
Sensitivity of the optimal subsidy



- The optimal subsidy ranges from **3–12%** across these parameter values
- Sensitivity is greatest with respect to the **external design premium**, which directly measures the size of the design spillover

Back to Pigovian subsidy

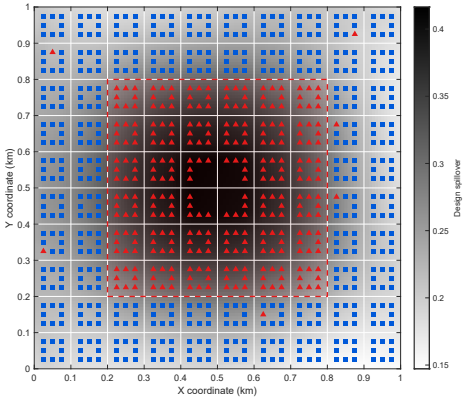
Mandatory District Map



- Visualizes the location of the mandatory design district
- Shows spatial clustering of distinctive buildings
- Useful for interpreting spillover and coordination effects

Back to Mandatory District

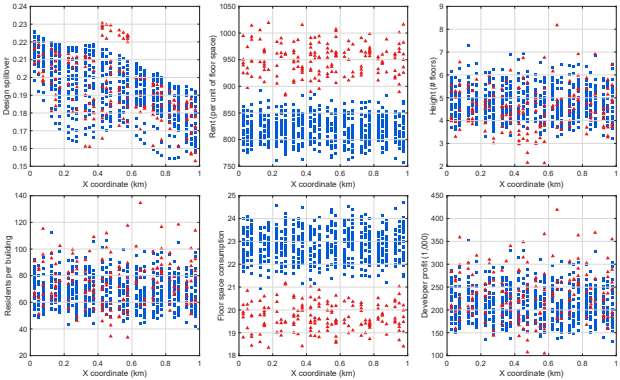
Mandatory District Map



- All distinctive buildings now in the district
- Many more distinctive buildings
- Profitable distinctive buildings **crowded out**

Back to Mandatory District

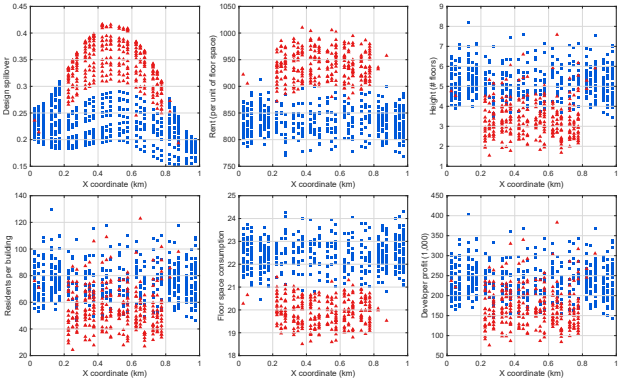
Mandatory District: Gradients



- When the mandatory district is large:
  - Distinctive share saturates
  - Returns diminish, congestion effects rise
- Welfare impact turns negative
  - Utility and profits decline
- Policy trade-off:
  - Small districts solve coordination
  - Large ones impose inefficiency

Back to Mandatory District

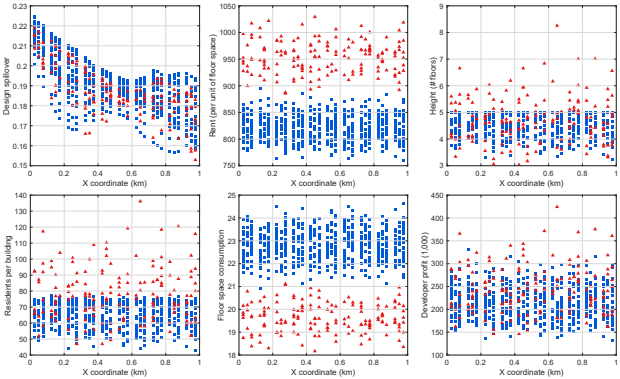
Mandatory District: Large-Scale Scenario



- When the mandatory district is large:
  - Distinctive share saturates
  - Returns diminish, congestion effects rise
- Welfare impact turns negative
  - Utility and profits decline
- Policy trade-off:
  - Small districts solve coordination
  - Large ones impose inefficiency

Back to Mandatory District

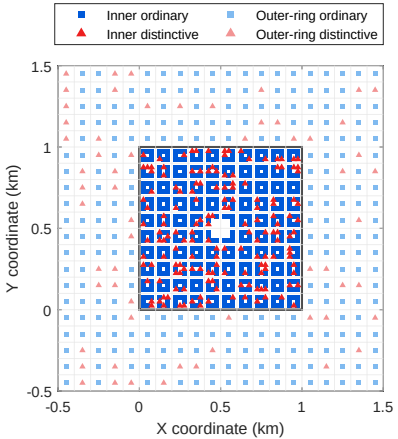
FAR incentives: Gradients



- With binding height constraints on ordinary buildings
  - Heights of distinctive buildings increase
  - Positive distinctive design premium persists
  - Some distinctive buildings generate large developer profits

Back to FAR incentives

Neighbourhood and fixed ring



Back to neighbourhood structure | Back to intuition

Survey evidence: agreement with the starchitect

Respondents and buildings classified relative to the starchitect:

Respondents	Buildings	Mean	Variance	Scale A_b	Shape ε
Similar tastes	Ranked high	70.05	404.11	55.73	5.14
Similar tastes	Ranked low	32.63	429.52	24.08	3.10
Different tastes	Ranked high	57.71	665.86	45.99	3.84
Different tastes	Ranked low	48.27	507.29	38.18	3.73

- Relative high/low scales: $55.73/24.08 = 2.31$ vs. $45.99/38.18 = 1.20$
  - Ratio of ratios: $2.31/1.20 \approx 1.92$, motivating $(A_D^1/A_O^1)/(A_D^2/A_O^2) = 2$
- $\beta^1/\beta^2 = 2$ remains an assumption, not a separate survey estimate

Back to heterogeneous workers

Heterogeneous workers: idiosyncratic tastes

- For group $k \in \{1, 2\}$, the joint CDF of taste shocks is
- $\Pr\left[a_i^k(\omega) \leq z_i \text{ for all } i\right] = \exp\left\{-\sum_{d\in\{O,D,\text{out}\}} \left(\sum_{i\in\mathcal{I}_d} z_i^{-\eta_k}\right)^{\varepsilon_k/\eta_k}\right\}$
  - $\eta_k \geq \varepsilon_k > 1$
- $a_i^k(\omega)$: worker's realised taste shock; $z_i > 0$: CDF threshold
- $\mathcal{I}_O, \mathcal{I}_D$: ordinary and distinctive buildings
  - Outside option is a singleton nest: $\mathcal{I}_{\text{out}} = \{\text{out}\}$
- η_k: substitution within designs; ε_k: across designs
  - If $\eta_k = \varepsilon_k$, shocks are independent across alternatives.
  - Each marginal is Fréchet: $\Pr[a_i^k \leq z] = \exp(-z^{-\varepsilon_k})$

Back to heterogeneous workers

Heterogeneous workers: location choice

- The probability that a group-k worker chooses building $i \in \mathcal{I}_d$ is

$$\pi_i^k = \frac{(v_i^k)^{\eta_k} \left[\sum_{j \in \mathcal{I}_d} (v_j^k)^{\eta_k}\right]^{\varepsilon_k/\eta_k - 1}}{\sum_{d' \in \{O,D\}} \left[\sum_{j \in \mathcal{I}_{d'}} (v_j^k)^{\eta_k}\right]^{\varepsilon_k/\eta_k} + (\bar{V}^k)^{\varepsilon_k}},$$

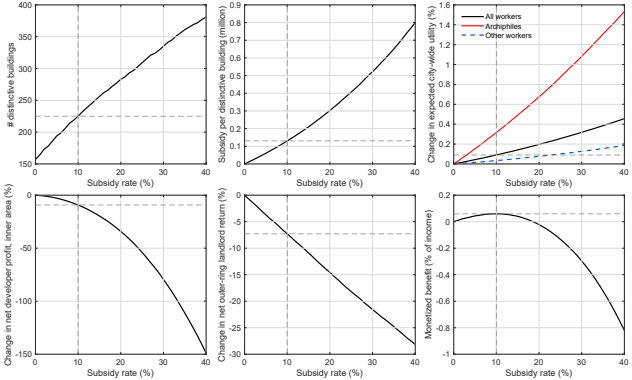
  with utility before the taste shock

$$v_i^k = \frac{A_d^k b_i^k e^{\beta^k D_i} w^k}{Q_i^{1-\alpha_k}}, \qquad A_O^k = 1.$$

- A_d^k: design preference; b_i^k: exogenous location amenity
- D_i: design spillover; Q_i: floor-space rent
- $\bar{V}^k$: outside-option utility index; residents $N_i^k = N^k \pi_i^k$

Back to heterogeneous workers

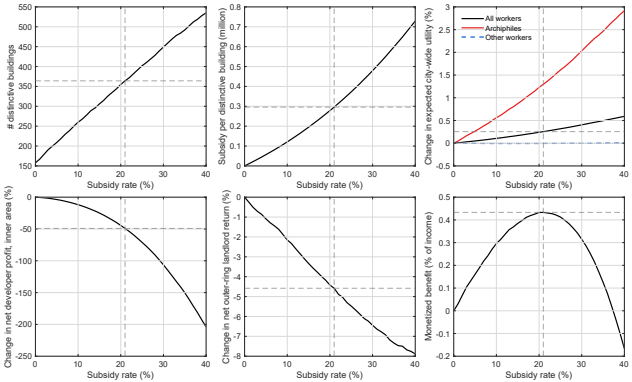
Two-worker subsidy: $\eta = 100$



Back to welfare by worker group

- Little within-group taste idiosyncrasy: aggregate results resemble the baseline.
- **Archiphiles benefit much more**
  - Utility gains at the optimum: 0.315% vs. 0.034% for others.

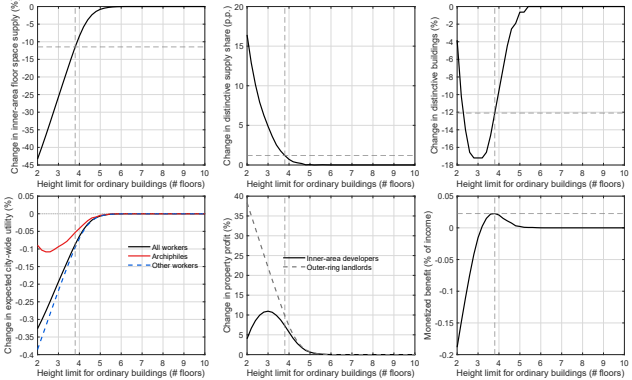
Two-worker subsidy: $\eta = 8$



Back to welfare by worker group

- Matching rent premia under lower η requires stronger spillover preferences, supporting larger subsidy gains.
- **Mainly archiphiles benefit**
  - For others, rent rises offset spillover gains. Lower location substitution limits spatial re-optimization.

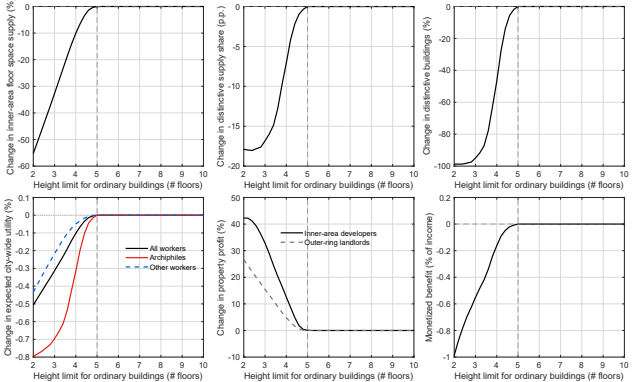
Two-worker FAR incentives: $\eta = 100$



Back to welfare by worker group

- Small net gain at a 3.8-floor cap: 0.023% of baseline income.
- **Both worker groups lose utility**
  - Higher property returns offset household losses in aggregate welfare.
- Landlords appropriate the welfare gain.

Two-worker FAR incentives: $\eta = 8$



Back to welfare by worker group

- Almost no net gain at the 5-floor optimum.
- **Tighter caps reduce distinctive supply**
  - Low location substitution limits relocation.
  - Tightening of distinctive supply increases rents enough for ordinary buildings to become *more* profitable

Two-worker distinctive district: full plaza

Outcome	$\eta = 100$	$\eta = 8$
Monetized net-benefit (% of baseline income)	0.00203	0.02334
Household utility change (%)	-0.00024	0.00345
Archiphiles: utility change (%)	0.00970	0.02802
Other workers: utility change (%)	-0.00273	-0.00269

- At $\eta = 8$, matching the internal design premium implies greater willingness to pay for distinctive design, making the mandate more attractive.
- **Archiphiles benefit much more; other workers do not gain.**

Back to welfare by worker group

Two-worker fully strategic super developer

Outcome	$\eta = 100$	$\eta = 8$
Monetized net-benefit (% of baseline income)	0.05462	0.42398
Household utility change (%)	0.01136	0.06483
Archiphiles: utility change (%)	0.11031	0.65035
Other workers: utility change (%)	-0.01338	-0.08155

- At $\eta = 8$, stronger inferred design and spillover preferences make coordinated distinctive provision more valuable.
- **Archiphiles gain; other workers lose**
  - For others, rent increases outweigh weaker amenity gains
  - Landlord developers extract a distinctive scarcity rent

Greedy outcome; global optimality is not established.
